This project was commissioned by the New Jersey Department of Banking and Insurance (DOBI). The authors would like to acknowledge Carol Miksad of DOBI, June Levy, Cheryl Malone, and Maria Lapolla of the New Jersey Division of Consumer Affairs, and the New Jersey Board of Medical Examiners for their assistance.

# **Availability of Physician Services in New Jersey: 2001-2006**

Susan Brownlee, Ph.D., Joel Cantor, Sc.D.

## **Executive Summary**

The New Jersey Medical Care Access and Responsibility and Patients First Act (N.J.S.A.2A:53A-37 et al.), signed into law in June 2004, requires the Commissioner of the Department of Banking and Insurance (DOBI) to determine which medical specialties are eligible for malpractice insurance premium subsidies. In making this determination, the law provides that the DOBI Commissioner may, in consultation with the Commissioner of Health and Senior Services, consider whether "...access to care for a particular specialty is threatened..." (C.17:30D-3(2)e). Rutgers Center for State Health Policy (CSHP) was commissioned by the NJ DOBI to provide information about the availability of physician services in New Jersey to assist the Commissioner in the implementation of this provision of the Act.

Detailed year-end American Medical Association (AMA) Physician Masterfile data for the years 2001, 2004, 2005, and 2006 were matched to New Jersey Board of Medical Examiners (BME) licensure lists for the respective years. Main practice specialties provided in the AMA Masterfile data were mapped as closely as possible to the Insurance Service Organization list of specialties provided by DOBI. New Jersey population data by county for the years 2001, 2004, 2005, and 2006 were used to calculate physician-to-population ratios by specialty. Ratios for specialties that serve specific demographic groups were limited to these groups. Measures of change from 2001 to 2006 and 2005 to 2006 were also computed. All analyses were limited to physicians designated by the AMA Masterfile as active in patient care with a main office location in New Jersey. The county of the main office location for each physician was used for the county-level analyses. To evaluate the adequacy of supply, New Jersey physician-to-patient ratios were compared to benchmark figures and U.S. supply. The benchmark figures are calculated as a ratio to the total population (i.e., not specific demographic groups), so New Jersey supply ratios were recalculated based on the total state population.

Overall, the total supply of patient care physicians in New Jersey increased over the study period by 1388 physicians or 1.4% (annual average change). In the most recent period (2005 to 2006), the number of NJ patient care physicians increased by 429 physicians or 2.1%. However, while the ratio of patient care physicians per 100,000 population in New Jersey increased by 0.8% between 2001 and 2006, there was a decrease (2.0%) for the most recent period (2005 to 2006).

The NJ supply per 100,000 population for 2006 (237.5) was below 2005 US physician supply levels (242.4) by just under 5 physicians per 100,000 population.

Several specialties and counties showed decreases or remained below US supply or below benchmarks. Family practice supply fell below the benchmarks and US supply in all years reported. Many surgical specialties, hospital-based specialties, and other specialties were below US supply across the four study years, whereas most medical subspecialties and primary care specialties were above US supply, with the exception of family practice, which was below US supply. Only about one in five specialties showed declining trends over the five year study period, including general practice, thoracic surgery, and general preventive (large declines, 2.5% and higher) and general internal medicine, obstetrics\gynecology, other internal medicine specialties, surgical specialties overall, general surgery, ophthalmology, and pathology (small declines, less than 2.5%). However, between 2005 and 2006, nearly two-thirds of the specialties declined, including 17 specialties with large declines and another 12 specialties with small declines.

In the county data, Cape May and Sussex counties were below the benchmarks for all four study years. Of these, only Cape May showed a declining trend between 2001 and 2006, and between 2005 and 2006. Gloucester and Salem counties were below the benchmarks in earlier years, but above in 2006, although Salem showed a decline between 2005 and 2006. Hudson county was below the benchmarks in 2001 and 2006, and also declined between 2005 and 2006. Eight additional counties were above the benchmarks but below US supply for the respective years, including Atlantic for 2001 and 2006, Burlington, Cumberland, Hunterdon, Ocean, Passaic, Union, and Warren across all four study years, and Somerset for 2006. Of these, only Hunterdon, Somerset, and Union showed declines between 2001 and 2006. Bergen and Morris counties (both above benchmarks and US supply) showed declines between 2001 and 2006. Atlantic, Essex, Mercer, Middlesex, and Somerset showed large declines between 2005 and 2006.

# **Availability of Physician Services in New Jersey: 2001-2006**

## **Introduction**

The New Jersey Medical Care Access and Responsibility and Patients First Act (N.J.S.A.2A:53A-37 et al.), signed into law in June 2004, requires the Commissioner of the Department of Banking and Insurance (DOBI) to determine which medical specialties are eligible for malpractice insurance premium subsidies. In making this determination, the law provides that the DOBI Commissioner may, in consultation with the Commissioner of Health and Senior Services, consider whether "...access to care for a particular specialty is threatened..." (C.17:30D-3(2)e). Rutgers Center for State Health Policy (CSHP) was commissioned by the NJ DOBI to provide information about the availability of physician services in New Jersey to assist the Commissioner in the implementation of this provision of the Act.

This report provides an update of results from the 2001-2005 report issued in May, 2006 (Cantor, Brownlee, & Huang, 2006). This revision contains updated year-end data for 2005 and new year-end data for 2006. There were no substantive changes in the overall conclusions of the earlier report as a result of the updated 2005 data. Data for 2002 are not included as CSHP was commissioned by DOBI to examine physician workforce supply for the years 2003, 2004, 2005, and 2006; CSHP had 2001 data on hand, so it was available and included in the report in order to show longer-term trends.

A comprehensive review of the existing literature on different methods for assessing the adequacy of physician supply was provided in the March 2005 report (Cantor, Brownlee, Sia, & Huang, 2005) and updated in April, 2007 (Sia, Cantor, Brownlee, & Abramo, 2007). In those reports, we concluded that although needs-based and demands-based measures have historically been used in physician workforce planning, benchmarking (comparing physician supply in different geographic regions or organized health care systems) is the preferred methodology.

## **Methods**

Detailed year-end AMA Physician Masterfile data for the years 2001, 2004, 2005, and 2006 were matched to New Jersey Board of Medical Examiners (BME) licensure lists for the respective years. Main practice specialties provided in the AMA Masterfile data were mapped as closely as possible to the Insurance Service Organization list of specialties provided by DOBI.

New Jersey population data by county for the years 2001, 2004, 2005, and 2006 were used to calculate physician-to-population ratios by specialty. Ratios for specialties that serve specific demographic groups were limited to these groups. Measures of change from 2001 to 2006 and 2005 to 2006 were also computed. All analyses were limited to physicians designated by the AMA Masterfile as active in patient care with a main office location in New Jersey. The county of the main office location for each physician was used for the county-level analyses. To evaluate the adequacy of supply, New Jersey physician-to-patient ratios were compared to benchmark figures (Weiner, 2004) and U.S. supply (Smart, 2006; Smart, 2007). The benchmark figures are calculated as a ratio to the total population (i.e., not specific demographic groups), so New Jersey supply ratios were recalculated based on the total state population.

## Results

In total, 48 specialties or subspecialties are evaluated in this report. Table 4 provides the final list of specialties used in the analysis (unless otherwise indicated, tables can be found at the end of the document). The column labeled “ISO-AMA Specialty” lists the 48 specialties and 6 summary categories for which ratios were calculated. The rows show how these specialties map to the ISO and AMA specialty lists. Note that it was not possible to create separate ratios for each ISO specialty due to the limitations of the AMA specialty classification.

For calculating physician-to-population ratios, New Jersey population data by county for the years 2001, 2004, 2005, and 2006 were purchased from Claritas, a commercial demographic research firm. Ratios for specialties that serve specific demographic groups were limited to these groups. Table 5 shows the age-gender groupings, appropriate for each specialty, that were used for population denominators in the calculation of physician-to-population ratios.

New Jersey statewide physician supply data are provided in Tables 6-11, and county by specialty data are provided in Tables 12-15. Long-term (2001 to 2006) and recent (2005 to 2006) percent changes are shown in each table.

Table 6 provides the number of active patient care physicians for each New Jersey county for 2001, 2004, 2005, and 2006, and the percentage change between these years. Table 7 provides physician-to-population ratios by county. Tables 8 and 9 display the number of New Jersey active patient care physicians by specialty in 2001, 2004, 2005, and 2006, and the percentage change in these numbers between these years. Statewide physician-to-population ratios by specialty for the respective years as well as the percentage change in the ratios are given in Tables 10 and 11. As noted above, population denominators vary by specialty.

Several conclusions can be drawn from the data. First, the total supply of patient care physicians in New Jersey increased over the study period by 1,388 physicians or 1.4% (annual average change). In the most recent period (2005 to 2006), the number of NJ patient care physicians increased by 429 physicians or 2.1% between 2005 and 2006 (Table 6). However, while the ratio of patient care physicians per 100,000 population in New Jersey increased by 0.8% between 2001 and 2006, there was a decrease (2.0%) for the most recent period (2005 to 2006) (Table 7) due to the over 4% increase in the population of the state of New Jersey during that time. The NJ supply per 100,000 population for 2006 (237.5) was just below 2005 US physician supply levels (242.4) by 4.9 physicians per 100,000 population.

All of the summary categories of physicians increased between 2001 and 2006 and for the most recent period (2005 to 2006) (Table 8). Specialties with the greatest absolute declines (over 2.5% average annual change) between 2001 and 2006 were general practice and general preventive medicine, while general surgery, thoracic surgery, other internal medicine specialties, obstetrics/gynecology, ophthalmology, and pathology showed more modest declines. Supply increased substantially (over 5% annualized) between 2001 and 2006 in nine specialties: gynecology only, geriatrics, pediatric subspecialties, endocrinology, hematology/oncology, infectious disease, vascular surgery, emergency medicine, and “other” specialties. The total number of pediatric surgeons, which are sub-specialties of surgical specialties, rose from 39 to 56, or 8.7% average annually, between 2001 and 2006, with a slightly faster growth rate (9.8%) between 2005 and 2006 (Table 9).

Because specialty-specific population denominators were used, changes in physician-to-population ratios vary slightly from those observed for overall supply counts (Table 10). About one in five specialty ratios declined between 2001 and 2006: general practice, general internal medicine, obstetrics/gynecology, other internal medicine specialties, surgical specialties overall, general surgery, ophthalmology, thoracic surgery, pathology, and general preventive. However, between 2005 and 2006, nearly two-thirds of the specialties declined, including five specialties with substantial declines (over 5%) (general practice, nephrology, other internal medicine specialties, thoracic surgery, and “other” specialties). The ratios for total pediatric surgeon supply increased substantially between 2001 and 2006 (8.0%), with a slightly slower growth rate (3.7%) between 2005 and 2006 (Table 11).

Tables 6 and 7 respectively show the number of active patient care physicians and ratio of physicians per 100,000 local population for each of New Jersey’s 21 counties. Some counties showed declines in overall supply in absolute and per population terms. Six counties experienced declines in physician supply ratios between 2001 and 2006 (Bergen, Cape May,

Hunterdon, Morris, Somerset, and Union). In addition, eight counties experienced a large (over 2.5%) decrease in supply ratios between 2005 and 2006 (Atlantic, Cape May, Essex, Hudson, Mercer, Middlesex, Somerset, and Union) and six more counties showed small declines.

Tables 2 and 3 identify physician specialties and counties that may be experiencing supply problems. Specifically, these tables use five measures to flag potential supply problems among specialties or counties: falling below one or more of the supply benchmarks published by Weiner (2004), falling below 2001 US average supply as measured by Weiner (2004); declining between 2001 and 2006; and declining between 2005 and 2006; the fifth measure displays 2004 US supply (Smart, 2006) and recently published data for 2005 US supply (Smart, 2007) for a more up-to-date comparison (these data can be found in Table 17). Average annual declines of supply ratios of 2.5% or more are flagged separately from other declines.

Comparisons of the New Jersey physician supply ratios to Weiner's national ratios required us to modify our calculations. Weiner did not employ specialty-specific population definitions, thus comparisons are all based on physicians per 100,000 total population regardless of specialty. The modified New Jersey ratios are provided in Table 16.

Although the supply ratios of most specialties in New Jersey were above Weiner's benchmarks (see Table 2), family practice and hematology/oncology supply fell below the benchmarks in all four study years. Pediatric subspecialties and emergency medicine were below the benchmarks in 2001, but have since rebounded. None of these specialties showed declining trends between 2001 and 2006.

Three broad groupings of specialties that were constructed for New Jersey had analogues in the Weiner report (primary care specialties, medical subspecialties, and surgical specialties). There was comparable 2004 and 2005 US supply data for the two other broad groupings of specialties (hospital based specialties and other specialties). Many surgical specialties, hospital-based specialties, and other specialties were below US supply across the four study years, whereas most medical subspecialties and primary care specialties were above US supply, with the exception of family practice (across all four study years), hematology/oncology (for 2001, 2004, and 2005), primary care specialties overall (for 2001, 2005, and 2006), and general practice (for 2005 and 2006), which were below US supply. Only about one in five specialties showed declining trends over the five year study period, including general practice, thoracic surgery, and general preventive (large declines, 2.5% and higher) and general internal medicine, obstetrics\gynecology, other internal medicine specialties, surgical specialties overall, general surgery, ophthalmology, and pathology (small declines, less than 2.5%). However, between 2005

and 2006, nearly two-thirds of the specialties declined, including 17 specialties with large declines (2.5% or more) and another 12 specialties with small declines.

In Table 3, which summarizes the county data, Cape May and Sussex counties were below the benchmarks for all four study years. Of these, only Cape May showed a declining trend between 2001 and 2006, and between 2005 and 2006. Gloucester and Salem counties were below the benchmarks in earlier years, but above in 2006, although Salem showed a decline between 2005 and 2006. Hudson County was below the benchmarks in 2001 and 2006, and also declined between 2005 and 2006. Eight additional counties were above the benchmarks but below US supply for the respective years, including Atlantic for 2001 and 2006, Burlington, Cumberland, Hunterdon, Ocean, Passaic, Union, and Warren across all four study years, and Somerset for 2006. Of these, only Hunterdon, Somerset, and Union showed declines between 2001 and 2006. Bergen and Morris counties (both above benchmarks and US supply) showed declines between 2001 and 2006. Atlantic, Essex, Mercer, Middlesex, and Somerset showed large declines between 2005 and 2006.

Table 12A-U and Table 13A-U respectively show the number of active patient care physicians by specialty and the ratios of physicians by specialty per 100,000 local population for each of New Jersey's 21 counties. Table 14 and Table 15 respectively show the number and ratios per 100,000 local population of active patient care pediatric surgery physicians for each of New Jersey's 21 counties. Care should be taken in interpreting these data as decreases or increases of a few physicians can appear quite large due to the small number of physicians in many specialties.

These data suggest potential local access problems in some counties and specialties. For example, in Cape May, the supply ratio of primary care physicians is only about 60% of that for the state. This is primarily due to very low supply ratios in Cape May for general internal medicine, obstetrics/gynecology, geriatrics, and pediatrics (both general pediatrics and pediatric subspecialties).

The county by specialty data is also useful for examining a particular specialty across counties. For example, the 2006 statewide supply for obstetrics/gynecology was 55.9 physicians per 100,000 women of child bearing age. But the supply ratios for obstetrics/gynecology varied widely across the state, from a low of 19.6 in Gloucester to a high of 83.2 in Bergen. Fourteen counties fell below the statewide average, and Gloucester (19.6), Cape May (21.5), and Sussex (21.8) showed particularly low supply ratios.

## **Conclusions**

Overall, the supply of patient care physicians with principal offices in New Jersey increased between 2001 and 2006. General practice, thoracic surgery, and general preventive medicine were the only specialties with substantial declines between 2001 and 2006. The decline in general practice is expected, reflecting a national shift in primary care training to family practice and general internal medicine. Seven other specialties showed modest declines between 2001 and 2006, and nearly two-thirds of specialties showed declines between 2005 and 2006.

Family practice and hematology/oncology supply fell below the benchmarks in all four years. Pediatric subspecialties and emergency medicine were below the benchmarks in 2001, but have since rebounded. None of these specialties showed declining trends between 2001 and 2006.

Although fourteen New Jersey counties were either below the benchmarks or US supply at some point during the four study years, only four of those (Cape May, Hunterdon, Somerset, and Union) showed declines in supply between 2001 and 2006. Cape May and Sussex counties were below the benchmarks for all four years. Of these, only Cape May showed a declining trend between 2001 and 2006, and between 2005 and 2006.

In summary, the physician supply of some specialties, particularly family practice and hematology/oncology, and in some rural counties remains below national averages or published benchmarks.

## **Limitations**

The calculations used in these results used counts of physicians as opposed to calculations of full-time-equivalents. Additionally, results are based on the location of each physician's main office. Some physicians work part time or work in multiple offices, counties, or states. The available data did not permit us to allocate physician supply more precisely.

Results by specialty were only examined for primary practice specialty. Some physicians work in more than one specialty. The results also did not take into account board certification in the primary specialty. Finally, the degree to which high-risk procedures are performed within certain specialties could not be determined from these data.

\* Population denominator is the total New Jersey population for all specialties.

<sup>a</sup> Ob/gyn are in surgery for this comparison.

<sup>n</sup> Not compared to Weiner as specialty definitions are not comparable.

\*\* 2001 NJ supply is compared to 2001 US supply (Weiner, 2004);

2004 NJ supply is compared to 2004 US supply (Smart, 2006) and 2005 and 2006 NJ supply are compared to 2005 US supply (Smart, 2007), which is the most recent, available national data.

\*\*\* Includes the estimated number of physicians whose practice location and specialty were unknown in each year.

Note: Data for 2002 are unavailable.

**Table 3: Comparison of 2001-2006 New Jersey Patient Care Physicians by County per 100,000 Population\* to 2001 Weiner Benchmarks and 2001/2004/2005 U.S. Supply**

\* Population denominator is the NJ total population for NJ data and the US total population for US data.

\*\* 2001 NJ supply is compared to 2001 US supply (Weiner, 2004);

2004 NJ supply is compared to 2004 US supply (Smart, 2006) and 2005 and 2006 NJ supply are compared to 2005 US supply (Smart, 2007), which is the most recent, available national data.

\*\*\* Includes the estimated number of physicians whose practice location and specialty were unknown in each year.

Note: Data for 2002 are unavailable.
